

Supervised learning

SUPERVISED LEARNING WITH SCIKIT-LEARN

Andreas Müller

Core developer, scikit-learn

What is machine learning?

- The art and science of:
 - Giving computers the ability to learn to make decisions from data
 - without being explicitly programmed!
- Examples:
 - Learning to predict whether an email is spam or not
 - Clustering wikipedia entries into different categories
- Supervised learning: Uses labeled data
- Unsupervised learning: Uses unlabeled data

Unsupervised learning

- Uncovering hidden patterns from unlabeled data
- Example:
 - Grouping customers into distinct categories (Clustering)

Reinforcement learning

- Software agents interact with an environment
 - Learn how to optimize their behavior
 - Given a system of rewards and punishments
 - Draws inspiration from behavioral psychology
- Applications
 - Economics
 - Genetics
 - Game playing
- AlphaGo: First computer to defeat the world champion in Go

Supervised learning

- Predictor variables/features and a target variable
- Aim: Predict the target variable, given the predictor variables
 - Classification: Target variable consists of categories
 - Regression: Target variable is continuous

The diagram illustrates the components of supervised learning. On the left, a table titled "Predictor variables" contains five rows of data for four features: sepal length, sepal width, petal length, and petal width. Row indices 0 through 4 are shown on the left. A blue arrow points from the "Predictor variables" title to the first row of the table. On the right, a vertical list titled "Target variable" shows the "species" for each row, all listed as "setosa". A blue arrow points from the "Target variable" title to the first entry in the list.

	sepal length (cm)	sepal width (cm)	petal length (cm)	petal width (cm)
0	5.1	3.5	1.4	0.2
1	4.9	3.0	1.4	0.2
2	4.7	3.2	1.3	0.2
3	4.6	3.1	1.5	0.2
4	5.0	3.6	1.4	0.2

Predictor variables

Target variable

species
setosa

Naming conventions

- Features = predictor variables = independent variables
- Target variable = dependent variable = response variable

Supervised learning

- Automate time-consuming or expensive manual tasks
 - Example: Doctor's diagnosis
- Make predictions about the future
 - Example: Will a customer click on an ad or not?
- Need labeled data
 - Historical data with labels
 - Experiments to get labeled data
 - Crowd-sourcing labeled data

Supervised learning in Python

- We will use scikit-learn/sklearn
 - Integrates well with the SciPy stack
- Other libraries
 - TensorFlow
 - keras

Let's practice!

The Iris dataset

Features:

- Petal length
- Petal width
- Sepal length
- Sepal width

Target variable: Species

- Versicolor
- Virginica
- Setosa

The Iris dataset in scikit-learn

```
from sklearn import datasets  
import pandas as pd  
import numpy as np  
import matplotlib.pyplot as plt  
plt.style.use('ggplot')  
iris = datasets.load_iris()  
type(iris)
```

```
sklearn.datasets.base.Bunch
```

```
print(iris.keys())
```

```
dict_keys(['data', 'target_names', 'DESCR', 'feature_names', 'target'])
```

The Iris dataset in scikit-learn

```
type(iris.data), type(iris.target)
```

```
(numpy.ndarray, numpy.ndarray)
```

```
iris.data.shape
```

```
(150, 4)
```

```
iris.target_names
```

```
array(['setosa', 'versicolor', 'virginica'], dtype='<U10')
```

Exploratory data analysis (EDA)

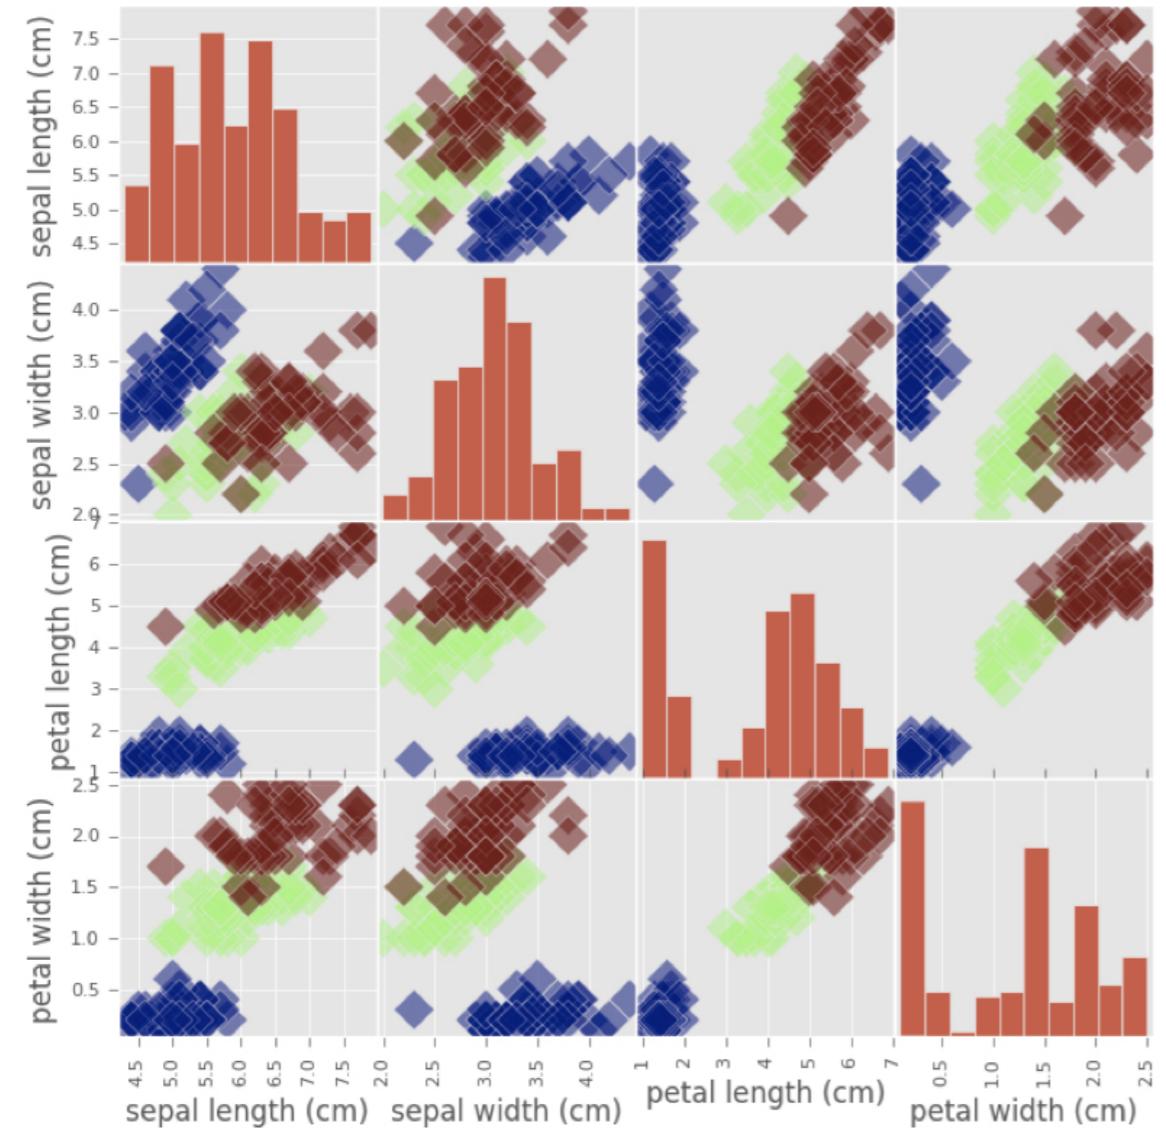

```
X = iris.data  
y = iris.target  
df = pd.DataFrame(X, columns=iris.feature_names)  
print(df.head())
```

	sepal length (cm)	sepal width (cm)	petal length (cm)	petal width (cm)
0	5.1	3.5	1.4	0.2
1	4.9	3.0	1.4	0.2
2	4.7	3.2	1.3	0.2
3	4.6	3.1	1.5	0.2
4	5.0	3.6	1.4	0.2

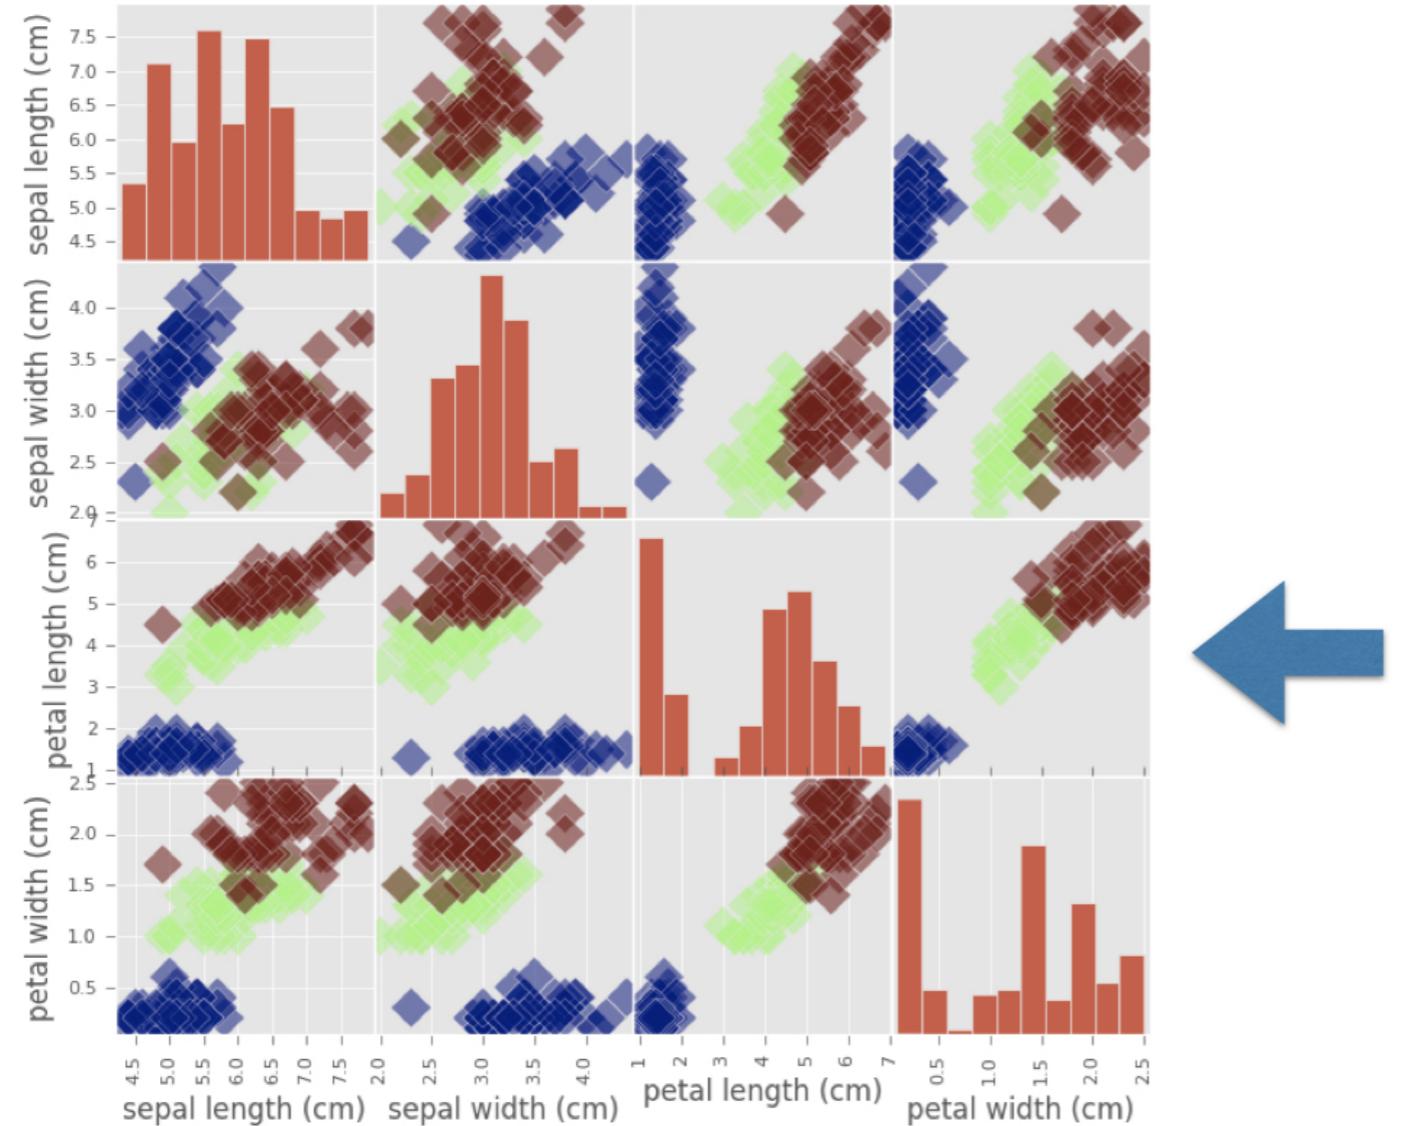

Visual EDA

```
_ = pd.scatter_matrix(df, c = y, figsize = [8, 8],  
                      s=150, marker = 'D')
```

k-Nearest Neighbors

- Basic idea: Predict the label of a data point by
 - Looking at the 'k' closest labeled data points
 - Taking a majority vote

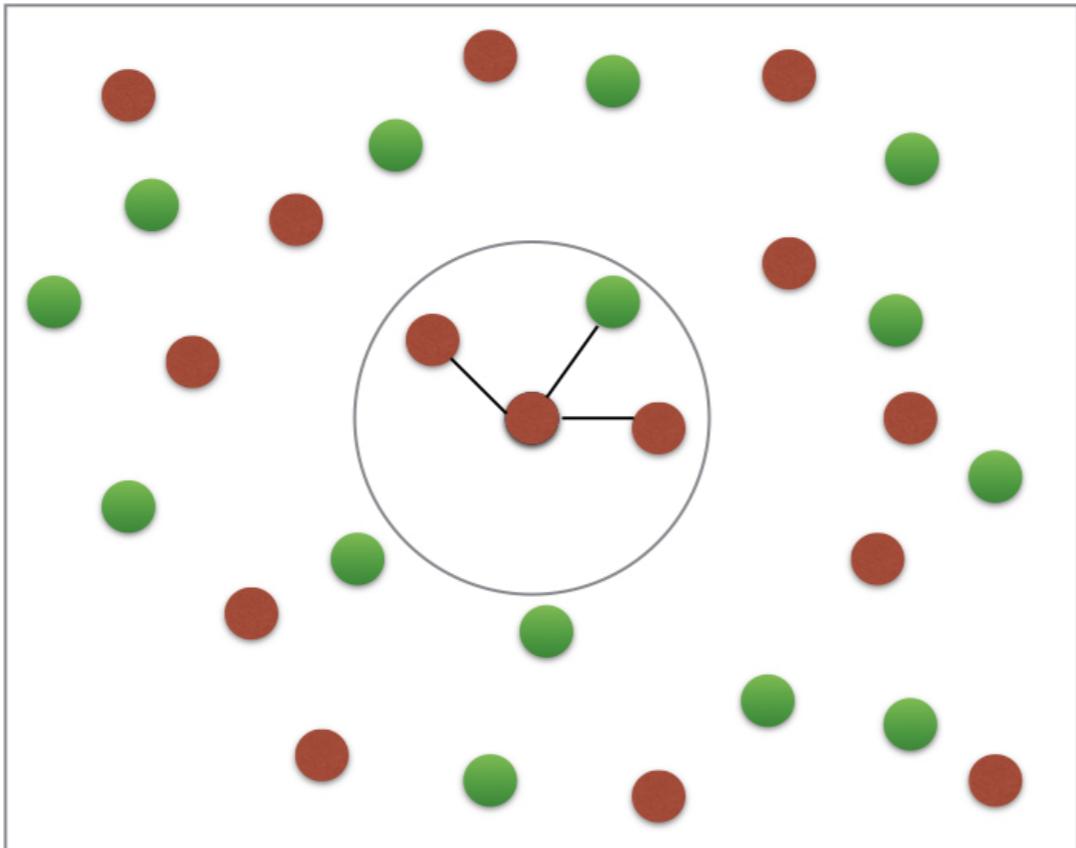

k-Nearest Neighbors

Scikit-learn fit and predict

- All machine learning models implemented as Python classes
 - They implement the algorithms for learning and predicting
 - Store the information learned from the data
- Training a model on the data = ‘fitting’ a model to the data
 - `.fit()` method
- To predict the labels of new data: `.predict()` method

Using scikit-learn to fit a classifier

```
from sklearn.neighbors import KNeighborsClassifier  
knn = KNeighborsClassifier(n_neighbors=6)  
knn.fit(iris['data'], iris['target'])
```

```
KNeighborsClassifier(algorithm='auto', leaf_size=30,  
metric='minkowski', metric_params=None, n_jobs=1,  
n_neighbors=6, p=2, weights='uniform')
```

```
iris['data'].shape
```

```
(150, 4)
```

```
iris['target'].shape
```

```
(150, )
```

Predicting on unlabeled data

```
prediction = knn.predict(X_new)
```

```
X_new.shape
```

```
(3, 4)
```

```
print('Prediction {}'.format(prediction))
```

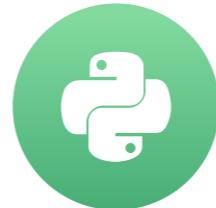

```
Prediction: [1 1 0]
```

Let's practice!

SUPERVISED LEARNING WITH SCIKIT-LEARN

Measuring model performance

SUPERVISED LEARNING WITH SCIKIT-LEARN

Hugo Bowne-Anderson
Data Scientist, DataCamp

Measuring model performance

- In classification, accuracy is a commonly used metric
- Accuracy = Fraction of correct predictions
- Which data should be used to compute accuracy?
- How well will the model perform on new data?

Measuring model performance

- Could compute accuracy on data used to fit classifier
- NOT indicative of ability to generalize
- Split data into training and test set
- Fit/train the classifier on the training set
- Make predictions on test set
- Compare predictions with the known labels

Train/test split

```
from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test =
    train_test_split(X, y, test_size=0.3,
                     random_state=21, stratify=y)
knn = KNeighborsClassifier(n_neighbors=8)
knn.fit(X_train, y_train)
y_pred = knn.predict(X_test)
print("Test set predictions:\n {}".format(y_pred))
```

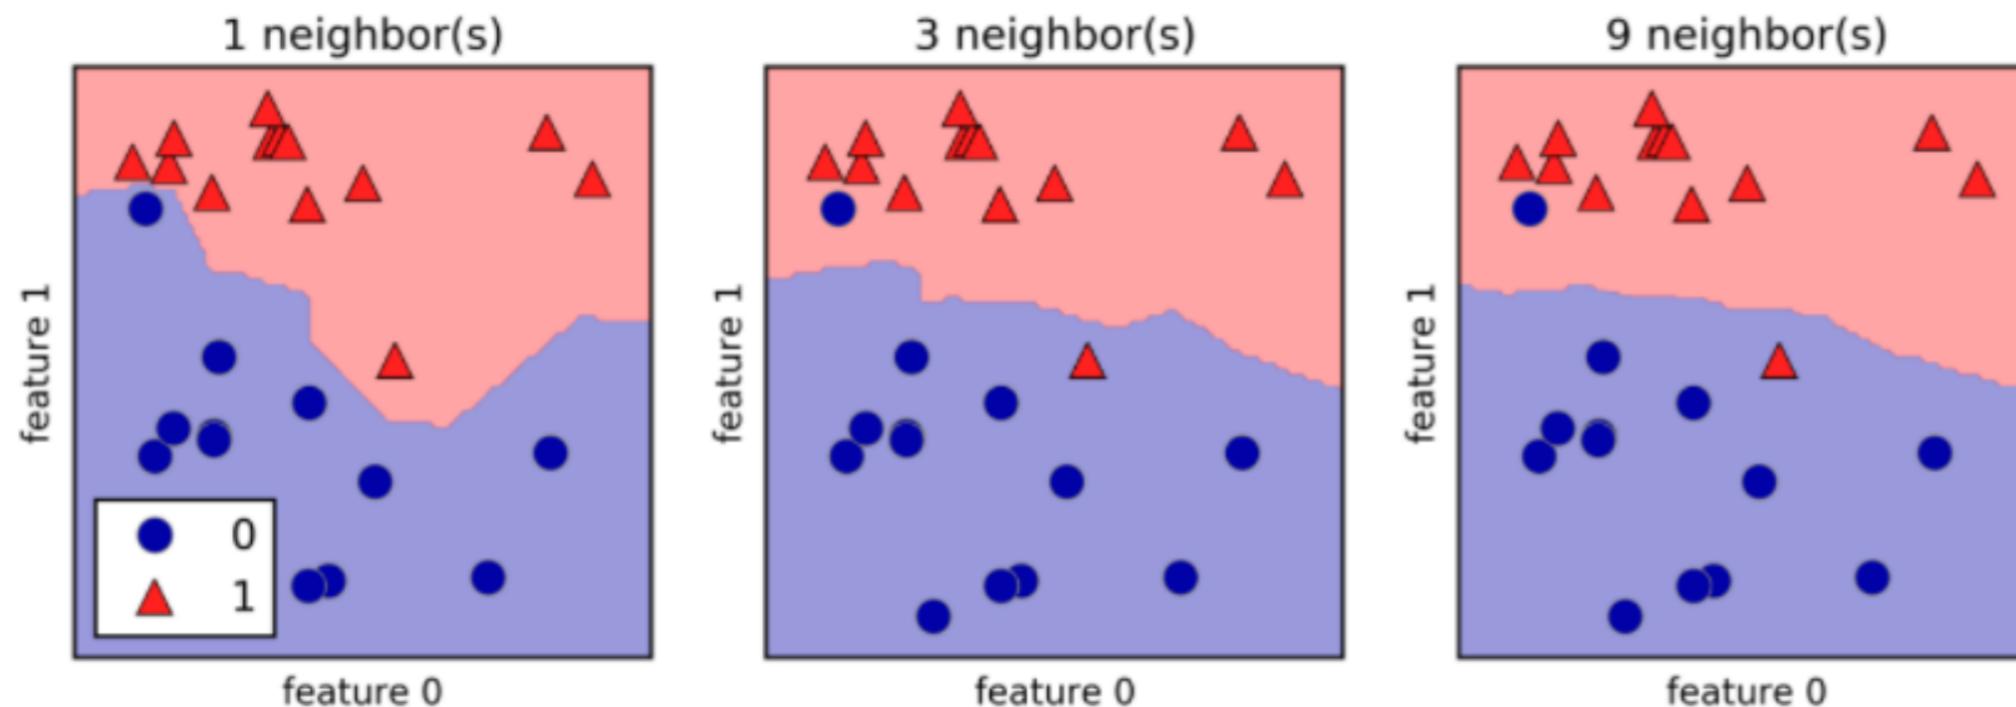

```
Test set predictions:
[2 1 2 2 1 0 1 0 0 1 0 2 0 2 0 0 0 1 0 2 2 2 0 1 1 1 0 0
 1 2 2 0 0 2 2 1 1 2 1 1 0 2 1]
```

```
knn.score(X_test, y_test)
```

```
0.9555555555555556
```

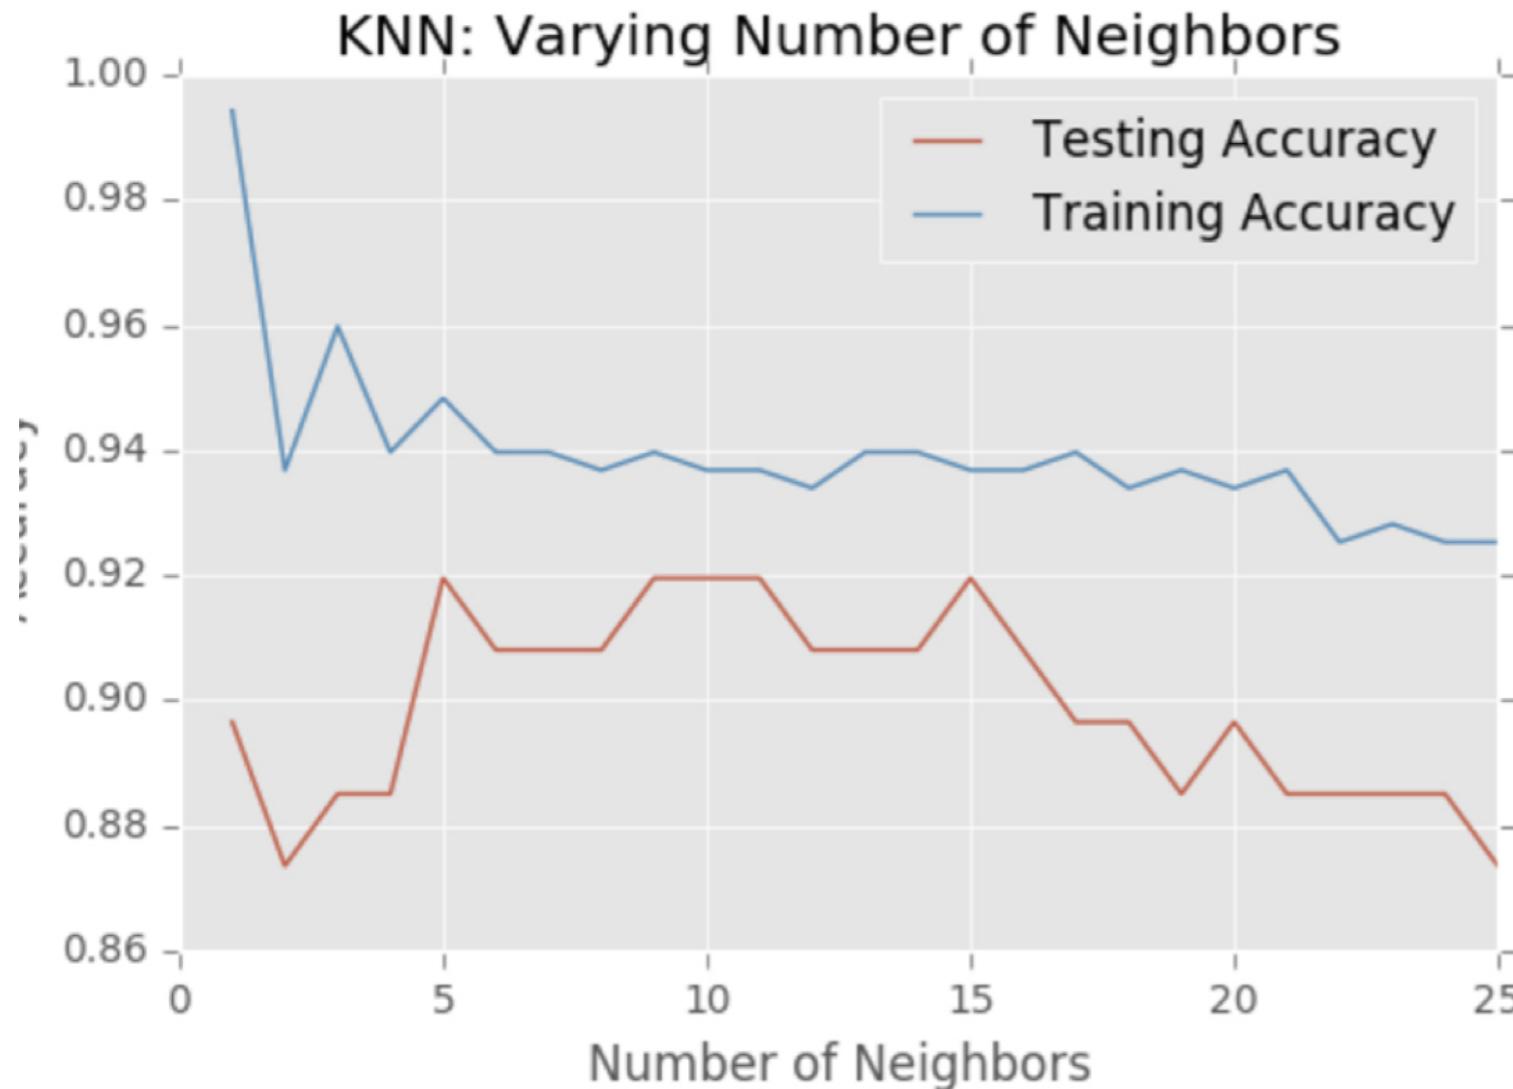

Model complexity

- Larger k = smoother decision boundary = less complex model
- Smaller k = more complex model = can lead to overfitting
